Theorem 1 Existence and Uniqueness Theorem (Theorem 3.2.1) Consider the initial value problem

$$
y^{\prime \prime}+p(t) y^{\prime}+q(t) y=g(t), \quad y\left(t_{0}\right)=y_{0}, \quad y^{\prime}\left(t_{0}\right)=y_{0}^{\prime}
$$

where $p, q$ and $g$ are continuous on an open interval $I$. Then there exists exactly one solution $y=\phi(t)$ of this problem, and the solution exists throughout the interval I.

Theorem 2 Principle of Superposition (Theorem 3.2.2) If $y_{1}$ and $y_{2}$ are two solutions of the differential equation

$$
L[y]=y^{\prime \prime}+p(t) y^{\prime}+q(t)=0,
$$

then the linear combination $y(t)=c_{1} y_{1}+c_{2} y_{2}$ is also a solution for any values of the constants $c_{1}$ and $c_{2}$.
Theorem 3 (Theorem 3.2.3) Suppose that $y_{1}$ and $y_{2}$ are two solutions of

$$
L[y]=y^{\prime \prime}+p(t) y^{\prime}+q(t) y=0
$$

and that the Wronskian

$$
W=y_{1} y^{\prime}{ }_{2}-y^{\prime}{ }_{1} y_{2},
$$

is not zero at the point $t_{0}$ where the initial conditions $y\left(t_{0}\right)=y_{0}, y^{\prime}\left(t_{0}\right)=y^{\prime}{ }_{0}$ are assigned. Then there is a choice of constant $c_{1}$ and $c_{2}$ for which $y=c_{1} y_{1}(t)+c_{2} y_{2}(t)$ satisfies the associated IVP.

Theorem 4 (Theorem 3.2.4) If $y_{1}$ and $y_{2}$ are two solutions of the DE:

$$
L[y]=y^{\prime \prime}+p(t) y^{\prime}+q(t) y=0
$$

and if there is a point $t_{0}$ where the Wronskian of $y_{1}$ and $y_{2}$ is nonzero, then the family of solutions

$$
y(t)=c_{1} y_{1}(t)+c_{2} y_{2}(t)
$$

with arbitrary coefficients $c_{1}$ and $c_{2}$ includes every solution of the $D E$.
Theorem 5 (Theorem 3.2.5) Consider the $D E$

$$
L[y]=y^{\prime \prime}+p(t) y^{\prime}+q(t) y=0
$$

whose coefficients $p, q$ are continuous on some open interval I. Choose some point $t_{0}$ in $I$. Let $y_{1}$ be the solution of the DE that also satisfies the initial conditions:

$$
y\left(t_{0}\right)=1, \quad y^{\prime}\left(t_{0}\right)=0
$$

and let $y_{2}$ be the solution of the DE that also satisfies the initial conditions:

$$
y\left(t_{0}\right)=0, \quad y^{\prime}\left(t_{0}\right)=1
$$

Then $y_{1}$ and $y_{2}$ form a fundamental set of solutions for the DE.

Here is a concept map of how the theorems relate. In what follows we have
DE: $\quad y^{\prime \prime}(t)+p(t) y^{\prime}(t)+q(t) y(t)=0$,
IVP: $\quad y^{\prime \prime}(t)+p(t) y^{\prime}(t)+q(t) y(t)=0, \quad y\left(t_{0}\right)=y_{0}, \quad y^{\prime}\left(t_{0}\right)=y_{0}^{\prime}$.
where $p, q$ and $g$ are continuous in an interval $I$.
Note that Theorem 3.2.1 also applies to nonhomogeneous linear differential equations.

A unique solution exists to the IVP (Theorem 3.2.1)

Two solutions to the DE are known, $\mathrm{y} 1(\mathrm{t})$ and $\mathrm{y} 2(\mathrm{t}) \quad$ (finding these solutions is majority of work in coming chapters)

Is Wronskian $\mathrm{W}(\mathrm{y} 1, \mathrm{y} 2)$ equal to zero?

Then $\mathrm{c} 1 \mathrm{y} 1(\mathrm{t})+\mathrm{c} 2 \mathrm{y} 2(\mathrm{t})$ is a solution to the IVP

Then $\mathrm{y}(\mathrm{t})=\mathrm{c} 1 \mathrm{y} 1(\mathrm{t})+\mathrm{c} 2 \mathrm{y} 2(\mathrm{t})$ is a general solution to the DE
(Theorem 3.2.4)

The DE always has a fundamental set of solutions
Theorem 6 Abel's Theorem (Theorem 3.2.6) If $y_{1}$ and $y_{2}$ are solutions of the differential equation

$$
L[y](t)=y^{\prime \prime}+p(t) y^{\prime}+q(t) y=0
$$

where $p$ and $q$ are continuous on an open interval $I$, then the Wronskian $W\left(y_{1}, y_{2}\right)(t)$ is given by:

$$
W\left(y_{1}, y_{2}\right)(t)=c \exp \left[-\int p(t) d t\right],
$$

where $c$ is a certain constant that depends on $y_{1}, y_{2}$, but not on $t$. Further, $W\left(y_{1}, y_{2}\right)(t)$ is either zero for all $t$ in $I$ (if $c=0)$ or else is never zero in I (if $c \neq 0)$.
